Why Python?

- Python is a widely used, general purpose programming language.
- Easy to start working with.
- Scientific computation functionality similar to Matlab and Octave.
- Used by major deep learning frameworks such as PyTorch and TensorFlow.

Topics

1. Why Python?
- 2. Setup**
3. Language Basics
4. Introduction to NumPy
5. Practical Python Tips
6. Other Great References

Code is in Courier New.

Command line input is prefixed with ``$``.

Output is prefixed with ``>>``.

Environment Management

- Problem

- Different versions of Python
- Countless Python packages and their dependencies
- Different projects require different packages
 - Even worse, different versions of the same package!

- Solution

- Keep multiple Python environments that are isolated from each other
- Each environment
 - Can use different Python version
 - Keeps its own set of packages (can specify package versions)
 - Can be easily replicated

Anaconda

- Anaconda is a popular Python environment/package manager
 - Install from <https://www.anaconda.com/download/>
 - Supports Windows, Linux, MacOS
 - Can create and manage different isolated environments

Basic workflow

Create a new environment

```
$ conda create -n <environment_name>
```

```
$ conda create -n <environment_name> python=3.7
```

With specific Python version

```
$ conda env create -f <environment.yml>
```

From environment file

Activate/deactivate environment

```
$ conda activate <environment_name>
```

```
<...do stuff...>
```

```
$ conda deactivate
```

Export environment

```
$ conda activate <environment_name>
```

```
$ conda env export > environment.yml
```

IDEs / text editors for Python

- PyCharm
- Visual Studio Code
- Sublime Text
- Atom
- Vim (for Linux)

Write a Python program in your IDE or text editor of choice.

In terminal, activate conda environment and run program with command:

```
$ python <filename.py>
```

Jupyter Notebook / Google Colab

- Jupyter Notebook
 - A Jupyter notebook lets you write and execute Python code locally in your web browser
 - Interactive, code re-execution, result storage, can interleave text, equations, and images
 - Can add conda environments to Jupyter notebook
- Google Colab
 - <https://colab.research.google.com/>
 - Google's hosted Jupyter notebook service, runs in the cloud, requires no setup to use, provides free access to computing resources including GPUs
 - Comes with many Python libraries pre-installed

Topics

1. Why Python?
2. Setup
- 3. Language Basics**
4. Introduction to NumPy
5. Practical Python Tips
6. Other Great References

Common Operations

<code>x = 10</code>		<code># Declaring two integer variables</code>
<code>y = 3</code>		<code># Comments start with hash</code>
<code>x + y</code>	<code>>> 13</code>	<code># Arithmetic operations</code>
<code>x ** y</code>	<code>>> 1000</code>	<code># Exponentiation</code>
<code>x / y</code>	<code>>> 3</code>	<code># Dividing two integers</code>
<code>x / float(y)</code>	<code>>> 3.333...</code>	<code># Type casting for float division</code>
<code>str(x) + "+"</code> <code>+ str(y)</code>	<code>>> "10 + 3"</code>	<code># Casting integer as string and string concatenation</code>

Built-in Values

`True, False`

`# Usual true/false values`

`None`

`# Represents the absence of something`

`x = None`

`# Variables can be assigned None`

`array = [1, 2, None]`

`# Lists can contain None`

`def func():`

`# Functions can return None`

`return None`

Built-in Values

<code>and</code>	# Boolean operators in Python written as plain English, as opposed to &&, , ! in C++
<code>or</code>	
<code>not</code>	
<code>if [] != [None]:</code>	# Comparison operators == and != check for equality/inequality, return true/false values
<code>print("Not equal")</code>	

Brackets → Indents

- Code blocks are created using indents, instead of brackets like in C++
- Indents can be 2 or 4 spaces, but should be consistent throughout file
- If using Vim, set this value to be consistent in your `.vimrc`

```
def sign(num):  
    # Indent level 1: function body  
    if num == 0:  
        # Indent level 2: if statement body  
        print("Zero")  
    elif num > 0:  
        # Indent level 2: else if statement body  
        print("Positive")  
    else:  
        # Indent level 2: else statement body  
        print("Negative")
```

Language Basics

Python is a strongly-typed and dynamically-typed language.

Strongly-typed: Interpreter always “respects” the types of each variable. [1]

Dynamically-typed: “A variable is simply a value bound to a name.” [1]

Execution: Python is first interpreted into bytecode (.pyc) and then compiled by a VM implementation into machine instructions. (Most commonly using C.)

[1] <https://wiki.python.org/moin/Why%20is%20Python%20a%20dynamic%20language%20and%20also%20a%20strongly%20typed%20language>

Language Basics

Python is a strongly-typed and dynamically-typed language.

Strongly-typed: Interpreter always “respects” the types of each variable. [1]

Dynamically-typed: “A variable is simply a value bound to a name.” [1]

Execution: Python is first interpreted into bytecode (.pyc) and then compiled by a VM implementation into machine instructions. (Most commonly using C.)

What does this mean for me?

[1] <https://wiki.python.org/moin/Why%20is%20Python%20a%20dynamic%20language%20and%20also%20a%20strongly%20typed%20language>

Language Basics

Python is a strongly-typed and dynamically-typed language.

Strongly-typed: Types will not be coerced silently like in JavaScript.

Dynamically-typed: Variables are names for values or object references. Variables can be reassigned to values of a different type.

Execution: Python is “slower”, but it can run highly optimized C/C++ subroutines which make scientific computing (e.g. matrix multiplication) really fast.

[1] <https://wiki.python.org/moin/Why%20is%20Python%20a%20dynamic%20language%20and%20also%20a%20strongly%20typed%20language>

Language Basics

Python is a strongly-typed and dynamically-typed language.

Strongly-typed: `1 + '1' → Error!`

Dynamically-typed: `foo = [1,2,3] ...later... foo = 'hello!'`

Execution: `np.dot(x, W) + b → Fast!`

[1] <https://wiki.python.org/moin/Why%20is%20Python%20a%20dynamic%20language%20and%20also%20a%20strongly%20typed%20language>

Collections: List

Lists are **mutable arrays** (think `std::vector`).

```
names = ['Zach', 'Jay']
names[0] == 'Zach'
names.append('Richard')
print(len(names) == 3) >> True
print(names) >> ['Zach', 'Jay', 'Richard']
names += ['Abi', 'Kevin']
print(names) >> ['Zach', 'Jay', 'Richard', 'Abi', 'Kevin']
names = [] # Creates an empty list
names = list() # Also creates an empty list
stuff = [1, ['hi', 'bye'], -0.12, None] # Can mix types
```

List Slicing

List elements can be accessed in convenient ways.

Basic format: `some_list[start_index:end_index]`

```
numbers = [0, 1, 2, 3, 4, 5, 6]
numbers[0:3] == numbers[:3] == [0, 1, 2]
numbers[5:] == numbers[5:7] == [5, 6]
numbers[:] == numbers == [0, 1, 2, 3, 4, 5, 6]
numbers[-1] == 6 # Negative index wraps around
numbers[-3:] == [4, 5, 6]
numbers[3:-2] == [3, 4] # Can mix and match
```

Collections: Tuples

Tuples are **immutable arrays**.

```
names = ('Zach', 'Jay') # Note the parentheses
```

```
names[0] == 'Zach'
```

```
print(len(names) == 2) >> True
```

```
print(names) >> ('Zach', 'Jay')
```

```
names[0] = 'Richard' >> TypeError: 'tuple' object does not  
support item assignment
```

```
empty = tuple() # Empty tuple
```

```
single = (10,) # Single-element tuple. Comma matters!
```

Collections: Dictionary

Dictionaries are **hash maps**.

```
phonebook = {} # Empty dictionary
phonebook = dict() # Also creates an empty dictionary
phonebook = {'Zach': '12-37'} # Dictionary with one item
phonebook['Jay'] = '34-23' # Add another item
print('Zach' in phonebook) >> True
print('Kevin' in phonebook) >> False
print(phonebook['Jay']) >> '34-23'
del phonebook['Zach'] # Delete an item
print(phonebook) >> {'Jay': '34-23'}
```

Loops

For loop syntax in Python

Instead of `for (i=0; i<10; i++)` syntax in languages like C++, use `range()`

```
for i in range(10):
```

```
    print(i)
```

```
>> 1
```

```
2...
```

```
9
```

```
10
```

Loops

To iterate over a list

```
names = ['Zach', 'Jay', 'Richard']  
for name in :  
    print('Hi ' + name + '!')
```

```
>> Hi Zach!  
    Hi Jay!  
    Hi Richard!
```

To iterate over indices and values

One way

```
for i in range(len(names)):  
    print(i, names[i])
```

```
>> 1 Zach  
    2 Jay  
    3 Richard
```

A different way

```
for i, name in enumerate(names):  
    print(i, name)
```

Loops

To iterate over a dictionary

```
phonebook = { 'Zach' : '12-37' , 'Jay' : '34-23' }
```

```
for name in phonebook:  
    print(name)
```

```
>> Jay  
     Zach
```

```
for number in phonebook.values():  
    print(number)
```

```
>> 12-37  
     34-23
```

```
for name, number in phonebook.items():  
    print(name, number)
```

```
>> Zach 12-37  
     Jay 34-23
```

Note: Whether dictionary iteration order is guaranteed depends on the version of Python.

Classes

```
class Animal(object):  
    def __init__(self, species, age):  
        self.species = species  
        self.age = age  
  
    def is_person(self):  
        return self.species  
  
    def age_one_year(self):  
        self.age += 1  
  
class Dog(Animal):  
    def age_one_year(self):  
        self.age += 7
```

Constructor `a = Animal('human', 10)`
Refer to instance with `self`
Instance variables are public

Invoked with `a.is_person()`

Inherits Animal's methods
Override for dog years

Model Classes

In the later assignments, you'll see and write model classes in PyTorch that inherit from `torch.nn.Module`, the base class for all neural network modules.

```
import torch.nn as nn

class Model(nn.Module):
    def __init__():
        ...

    def forward():
        ...
```

Installing Packages

pip installs Python packages, conda installs packages which may contain software written in any language

Issues may arise when using pip and conda together. It is best practice to first use conda to install as many packages as possible and use pip to install remaining packages after. [1]

```
conda install -n myenv [package_name][=optional version number]
```

Install packages using pip in a conda environment (necessary when package not available through conda)

```
conda install -n myenv pip                                # Install pip in environment
```

```
conda activate myenv                                     # Activate environment
```

```
pip install                                              # Install package
```

```
[package_name][==optional version number]
```

```
pip install -r <requirements.txt>                       # Install packages from file
```

[1] <https://docs.conda.io/projects/conda/en/latest/user-guide/tasks/manage-environments.html#using-pip-in-an-environment>

Importing Package Modules

```
# Import 'os' and 'time' modules
```

```
import os, time
```

```
# Import under an alias
```

```
import numpy as np
```

```
np.dot(x, y)                # Access components with pkg.fn
```

```
# Import specific submodules/functions
```

```
from numpy import linalg as la, dot as matrix_multiply
```

```
# Can result in namespace collisions...
```

Topics

1. Why Python?
2. Setup
3. Language Basics
- 4. Introduction to NumPy**
5. Practical Python Tips
6. Other Great References

NumPy

Optimized library for matrix and vector computation.

Makes use of C/C++ subroutines and memory-efficient data structures.

(Lots of computation can be efficiently represented as vectors.)

Main data type: `np.ndarray`

This is the data type that you will use to represent matrix/vector computations.

Note: constructor function is `np.array()`

np.ndarray

```
x = np.array([1,2,3])           >> [1 2 3]
y = np.array([[3,4,5]])         >> [[3 4 5]]
z = np.array([[6,7],[8,9]])     >> [[6 7] [8 9]]
```

```
print(x,y,z)
```

```
print(x.shape)           >> (3,)           A 1-D vector!
print(y.shape)           >> (1,3)          A (row) vector!
print(z.shape)           >> (2,2)          A matrix!
```

Note: shape (N,) != (1, N) != (N, 1)

np.ndarray Operations

Reductions: `np.max`, `np.min`, `np.amax`, `np.sum`, `np.mean`, ...

Always reduces along an axis! (Or will reduce along all axes if not specified.)

(You can think of this as “collapsing” this axis into the function’s output.)

```
# shape: (3, 2)
```

```
x = np.array([[1,2],[3,4],[5, 6]])
```

```
# shape: (3,)
```

```
print(np.max(x, axis = 1))
```

```
>> [2 4 6]
```

```
# shape: (3, 1)
```

```
print(np.max(x, axis = 1, keepdims = True))
```

```
>> [[2] [4] [6]]
```

np.ndarray Operations

Matrix Operations: `np.dot`, `np.matmul`, `np.linalg.norm`, `.T`, `+`, `...`

Infix operators (i.e. `+`, `-`, `*`, `**`, `/`) are element-wise.

Element-wise product (Hadamard product) of matrix A and B, $A \circ B$, can be computed:

`A * B`

Dot product and **matrix vector product** (between 1-D array vectors), can be computed:

`np.dot(u, v)`

`np.dot(x, W)`

Matrix product / multiplication of matrix A and B, AB , can be computed:

`np.matmul(A, B)` or `A @ B`

`np.dot()` can also be used for matrix multiplication, but if A and B are both 2-D arrays, `np.matmul()` is preferred.

Transpose with `x.T`

Note: SciPy and `np.linalg` have many, many other advanced functions that are very useful!

Indexing

```
x = np.random.random((3, 4))    # Random (3,4) matrix

x[:]                             # Selects everything in x

x[np.array([0, 2]), :]          # Selects the 0th and 2nd rows

x[1, 1:3]                        # Selects 1st row as 1-D vector

                                # and 1st through 2nd elements

x[x > 0.5]                       # Boolean indexing

x[:, :, np.newaxis]             # 3-D vector of shape (3, 4, 1)
```

Note: Selecting with an ndarray or range will preserve the dimensions of the selection.

Broadcasting

```
x = np.random.random((3, 4))      # Random (3, 4) matrix
y = np.random.random((3, 1))      # Random (3, 1) vector
z = np.random.random((1, 4))      # Random (1, 4) vector

x + y  # Adds y to each column of x
x * z  # Multiplies z (element-wise) with each row of x
```

Note: If you're getting an error, print the shapes of the matrices and investigate from there.

Broadcasting (visually)

1	2	3	4
5	6	7	8
9	10	11	12

x

+

1	1	1	1
2	2	2	2
3	3	3	3

y

2	3	4	5
7	8	9	10
12	13	14	15

1	2	3	4
5	6	7	8
9	10	11	12

x

*

1	2	3	4
1	2	3	4
1	2	3	4

z

1	2	3	4
5	12	21	32
9	30	33	48

Broadcasting (generalized)

When operating on two arrays, NumPy compares their shapes element-wise. It starts with the trailing (i.e. rightmost) dimensions and works its way left. Two dimensions are **compatible** when

1. they are equal, or
2. one of them is 1 (in which case, elements on the axis are repeated along the dimension)

```
a = np.random.random( (3, 4) )      # Random (3, 4) matrix
b = np.random.random( (3, 1) )      # Random (3, 1) vector
c = np.random.random( (3, ) )       # Random (3, ) vector
```

What do the following operations give us? What are the resulting shapes?

`b + b.T`

`a + c`

`b + c`

Efficient NumPy Code

Avoid explicit for-loops over indices/axes at all costs.

For-loops will dramatically slow down your code (~10-100x).

```
for i in range(x.shape[0]):           x **= 2
```

```
    for j in range(x.shape[1]):
```

```
        x[i,j] **= 2
```

```
for i in range(100, 1000):
```

```
    x[np.arange(100,1000), :] += 5
```

```
    for j in range(x.shape[1]):
```

```
        x[i, j] += 5
```

Topics

1. Why Python?
2. Setup
3. Language Basics
4. Introduction to NumPy
- 5. Practical Python Tips**
6. Other Great References

List Comprehensions

- Similar to `map()` from functional programming languages.
- Can improve readability & make the code succinct.
- Format: `[func(x) for x in some_list]`

Following are equivalent:

```
squares = []  
for i in range(10):  
    squares.append(i**2)
```

—

```
squares = [i**2 for i in range(10)]
```

Can be conditional:

```
odds = [i**2 for i in range(10) if i%2 == 1]
```

Convenient Syntax

Multiple assignment / unpacking iterables

```
age, name, pets = 20, 'Joy', ['cat']  
x, y, z = ('Tensorflow', 'PyTorch', 'Chainer')
```

Returning multiple items from a function

```
def some_func():  
    return 10, 1  
ten, one = some_func()
```

Joining list of strings with a delimiter

```
", ".join([1, 2, 3]) == '1, 2, 3'
```

String literals with both single and double quotes

```
message = 'I like "single" quotes.'  
reply = "I prefer 'double' quotes."
```

Debugging Tips

Python has an interactive shell where you can execute arbitrary code.

- Great replacement for TI-84 (no integer overflow!)
- Can import any module (even custom ones in the current directory)
- Try out syntax you're unsure about and small test cases (especially helpful for matrix operations)

```
$ python
Python 3.9.7 (default, Sep 16 2021, 08:50:36)
[Clang 10.0.0 ] :: Anaconda, Inc. on darwin
>> import numpy as np
>> A = np.array([[1, 2], [3, 4]])
>> B = np.array([[3, 3], [3, 3]])
>> A * B
[[3 6]
 [9 12]]
>> np.matmul(A, B)
[[9 9]
 [21 21]]
```

Debugging Tools

Code	What it does
<code>array.shape</code>	Get shape of NumPy array
<code>array.dtype</code>	Check data type of array (for precision, for weird behavior)
<code>type(stuff)</code>	Get type of variable
<code>import pdb; pdb.set_trace()</code>	Set a breakpoint [1]
<code>print(f'My name is {name}')</code>	Easy way to construct a string to print

[1] <https://docs.python.org/3/library/pdb.html>

Common Errors

ValueError(s) are often caused by **mismatch of dimensions** in broadcasting or matrix multiplication

If you get this type of error, a good first step to debugging the issue is to print out the shape of relevant arrays to see if they match what you expect.

`array.shape`
